Project Falcon Quality Playbook

Quality Assurance (QA) Responsibilities

QA focuses on the process. The goal is to prevent defects and improve the testing process.

- Establish and improve quality guidelines and testing practices within the team.
- Analyze requirements and design materials early to detect unclear or missing details before development starts.
- Monitor the development process to make sure agreed coding and review practices are followed.
- Take part in sprint retrospectives and suggest improvements to make the team's workflow more effective.

Quality Control (QC) Responsibilities

QC focuses on the product. The goal is to find existing problems or bugs by testing the finished product.

- Create and run test cases for completed features.
- Report bugs and check them after they are fixed.
- Perform regression testing after bug fixes to make sure existing features still work correctly.
- Check if the product meets the given requirements.

Our Guiding Principles

1. Early Testing: We will start testing from the requirements stage. We chose this principle because finding problems early helps us fix them faster and reduces the risk of bigger issues later.
2. Defect Clustering: We will focus more on areas where bugs are more likely to happen. We chose this principle because it helps us spend more testing time on high-risk parts of the product.
3. Exhaustive Testing is Impossible: We will prioritize the most important test cases instead of trying to test every possible scenario. We chose this principle because testing every possible case is not practical, so we need to focus on the most important areas.
